Input Modeling Driving Force for a Simulation Model

Radu Trîmbițaș

Faculty of Math and CS - UBB

1st Semester 2010-2011

Purpose and Overview

- The quality of the output is no better than the quality of inputs.
- We will discuss the 4 steps of input model development:
 - Collect data from the real system
 - Identify a probability distribution to represent the input process
 - Choose parameters for the distribution
 - Evaluate the chosen distribution and parameters for goodness of fit.

Data Collection

- One of the biggest tasks in solving a real problem.
 GIGO garbage-in-garbage-out
- Suggestions that may enhance and facilitate data collection:
 - Plan ahead: begin by a practice or pre-observing session, watch for unusual circumstances
 - Analyze the data as it is being collected: check adequacy
 - Combine homogeneous data sets, e.g. successive time periods, during the same time period on successive days
 - Be aware of data censoring: the quantity is not observed in its entirety, danger of leaving out long process times
 - Check for relationship between variables, e.g. build scatter diagram
 - Check for autocorrelation
 - Collect input data, not performance data

Histograms

- A frequency distribution or histogram is useful in determining the shape of a distribution
- The number of class intervals depends on:
 - The number of observations
 - The dispersion of the data
 - Suggested: the square root of the sample size or (Sturges' rule)

 $k = \lfloor 1 + 3.322 \log_{10} n \rfloor$

- For continuous data:
 - Corresponds to the probability density function of a theoretical distribution
- For discrete data:
 - Corresponds to the probability mass function
- If few data points are available: combine adjacent cells to eliminate the ragged appearance of the histogram

Selecting the Family of Distributions

- A family of distributions is selected based on:
 - The context of the input variable
 - Shape of the histogram
- Frequently encountered distributions:
 - Easier to analyze: exponential, normal and Poisson

- 日本 - 1 日本 - 日本 - 日本 - 日本

Harder to analyze: beta, gamma and Weibull

Time-Series Input Models

Selecting the Family of Distributions II

Use the physical basis of the distribution as a guide, for example:

- Binomial: # of successes in n trials
- Poisson: # of independent events that occur in a fixed amount of time or space
- Normal: dist'n of a process that is the sum of a number of component processes
- Exponential: time between independent events, or a process time that is memoryless
- Weibull: time to failure for components
- Discrete or continuous uniform: models complete uncertainty
- Triangular: a process for which only the minimum, most likely, and maximum values are known

Quantile-Quantile Plots

- Q-Q plot is a useful tool for evaluating distribution fit
- If X is a random variable with cdf F, then the q-quantile of X is the γ such that

$$F(\gamma) = P(X \le \gamma) = q, \qquad q \in [0, 1]$$

When F is invertible, $\gamma = F^{-1}(q)$.

Let {x_i : i = 1, 2, ..., n} be a sample of data from X and {y_j : j = 1, 2, ..., n} be the observations in ascending order; then an approximation of y_j, where j is the ranking or order number, is given by

$$y_j \approx F^{-1}\left(\frac{j-0.5}{n}\right)$$

- The plot of y_j versus $F^{-1}\left(\frac{j-0.5}{n}\right)$ is
 - Approximately a straight line if F is a member of an appropriate family of distributions
 - The line has slope 1 if F is a member of an appropriate family of distributions with appropriate parameter values.

Models

Q-Q plot - Example

Example

Check whether the door installation times follows a normal distribution. Observation sorted in increasing orders

j	Value	j	Value	j	Value
1	99.55	6	99.98	11	100.26
2	99.56	7	100.02	12	100.27
5	99.62	8	100.06	13	100.33
4	99.65	9	100.17	14	100.41
5	99.79	10	100.23	15	100.47

 y_j are plotted versus $F^{-1}((j-0.5)/n)$ where F has a normal distribution with the sample mean (99.99 sec) and sample variance (0.28322 sec²).

Quantile-Quantile Plots

- Consider the following while evaluating the linearity of a q-q plot:
 - The observed values never fall exactly on a straight line
 - The ordered values are ranked and hence not independent, unlikely for the points to be scattered about the line
 - Variance of the extremes is higher than the middle. Linearity of the points in the middle of the plot is more important.
- Q-Q plot can also be used to check homogeneity
 - Check whether a single distribution can represent both sample sets
 - Plotting the order values of the two data samples against each other

Time-Series Input Models

Parameter Estimation I

- Next step after selecting a family of distributions
- If observations in a sample of size n are X₁, X₂,..., X_n (discrete or continuous), the sample mean and variance are:

If the data are discrete and have been grouped in a frequency distribution:

$$\overline{X} = \frac{\sum_{j=1}^{n} f_j X_j}{n}, \qquad S^2 = \frac{\sum_{i=1}^{n} f_i X_j^2 - n \overline{X}^2}{n-1}$$

where f_j is the observed frequency of value X_j

Parameter Estimation II

When raw data are unavailable (data are grouped into class intervals), the approximate sample mean and variance are:

$$\overline{X} = \frac{\sum_{j=1}^{c} f_j m_j}{n}, \qquad S^2 = \frac{\sum_{i=1}^{c} f_j m_j^2 - n \overline{X}^2}{n-1}$$

where f_j is the observed frequency of in the jth class interval, m_j is the midpoint of the *j*th interval, and *c* is the number of class intervals

 A parameter is an unknown constant, but an estimator is a statistic.

Parameter Estimation III

Vehicle Arrival Example (continued): Table in the histogram example 1 can be analyzed to obtain:

$$n = 100, k = 12,$$

 $f_1 = 12, X_1 = 0, f_2 = 10, X_2 = 1, \dots$
 $\sum_{j=1}^{k} f_j X_j = 364, \qquad \sum_{j=1}^{k} f_j X_j^2 = 2080$

Sample mean and variance

$$\overline{X} = \frac{364}{100} = 3.64$$

 $S^2 = \frac{2080 - 100 \cdot 3.64^2}{99} = 7.63$

Goodness-of-Fit Tests

- Conduct hypothesis testing on input data distribution using:
 - Kolmogorov-Smirnov test
 - Chi-square test
- No single correct distribution in a real application exists.
 - If very little data are available, it is unlikely to reject any candidate distributions
 - If a lot of data are available, it is likely to reject all candidate distributions

Multivariate and Time-Series Input Models

Covariance and Correlation Multivariate Input Models

Time-Series Input Models

Chi-Square test I

- Intuition: comparing the histogram of the data to the shape of the candidate density or mass function
- Valid for large sample sizes when parameters are estimated by maximum likelihood
- By arranging the n observations into a set of k class intervals or cells, the test statistics is:

$$\chi_0^2 = \sum_{i=1}^k \frac{(O_i - E_i)^2}{E_i}$$

which approximately follows the chi-square distribution with k - s - 1 degrees of freedom, where s = # of parameters of the hypothesized distribution estimated by the sample statistics.

- O_i observed frequency, E_i expected frequency
- $E_i = np_i$, it must hold $E_i > 5$ (minimum requirement)

Input Modeling

Radu Trîmbițaș

Multivariate and Time-Series Input Models

Covariance and Correlation Multivariate Input Models

Time-Series Input Models

Chi-Square test II

The hypothesis of a chi-square test is:

- ► H₀: The random variable, X, conforms to the distributional assumption with the parameter(s) given by the estimate(s).
- ► *H*₁: The random variable X does not conform.
- If the distribution tested is discrete and combining adjacent cell is not required (so that E_i > minimum requirement):
- Each value of the random variable should be a class interval, unless combining is necessary, and

$$p_i = p(x_i) = P(X = x_i)$$

Kolmogorov-Smirnov Test

- Intuition: formalize the idea behind examining a q-q plot
- Recall from previous lectures:
 - ► The test compares the continuous cdf, F(x), of the hypothesized distribution with the empirical cdf, F_N(x), of the N sample observations.
 - Based on the maximum difference statistics $D = \max |F(x) - \overline{F}_N(x)|$
- A more powerful test, particularly useful when:
 - Sample sizes are small,
 - No parameters have been estimated from the data.
- When parameter estimates have been made:
 - Critical values in tables are biased, too large.
 - More conservative, i.e., smaller Type I error than specified.

p-Values and "Best Fits" I

p-value for the test statistics

- ► The significance level at which one would just reject H₀ for the given test statistic value.
- A measure of fit, the larger the better
- Large p-value: good fit
- Small p-value: poor fit
- Vehicle Arrival Example (cont.):
 - ► H₀: data is Possion
 - Test statistics: $\chi_0^2 = 27.68$, with 5 degrees of freedom
 - ▶ p-value = 0.00004, meaning we would reject *H*₀ with 0.00004 significance level, hence Poisson is a poor fit.
- p-value is important in practical implementation of statistical tests in software packges and products

p-Values and "Best Fits" II

- Many software use p-value as the ranking measure to automatically determine the "best fit". Things to be cautious about:
 - Software may not know about the physical basis of the data, distribution families it suggests may be inappropriate.
 - Close conformance to the data does not always lead to the most appropriate input model.
 - p-value does not say much about where the lack of fit occurs

 Recommended: always inspect the automatic selection using graphical methods.

Fitting a Non-stationary Poisson Process I

- Fitting a NSPP to arrival data is difficult, possible approaches:
 - Fit a very flexible model with lots of parameters or
 - Approximate constant arrival rate over some basic interval of time, but vary it from time interval to time interval.
- Suppose we need to model arrivals over time [0,T], our approach is the most appropriate when we can:
 - Observe the time period repeatedly and
 - Count arrivals / record arrival times.

Fitting a Non-stationary Poisson Process II

The estimated arrival rate during the *i*th time period is:

$$\widehat{\lambda}(t) = rac{1}{n\Delta t} \sum_{j=1}^{n} C_{ij}$$

where n = # of observation periods, $\Delta t =$ time interval length, $C_{ij} = \#$ of arrivals during the ith time interval on the jth observation period

• Example: Divide a 10-hour business day [8am,6pm] into equal intervals k = 20 whose length $\Delta t = 1/2$, and observe over n = 3 days

1	Number of Arrivals			Estimated Arrival		ľ
Time Period	Day 1	Day 2	Day 3	Rate (arrivals/hr)		
8:00 - 8:00	12	14	10	24	For instance, 1/3/0 5)*(23+26+32)	P
8:30 - 9:00	23	26	32	54	= 54 arrivals/hour	
9:00 - 9:30	27	18	32	52

Multivariate and Time-Series Input Models

Selecting Model without Data I

- If data is not available, some possible sources to obtain information about the process are:
 - Engineering data: often product or process has performance ratings provided by the manufacturer or company rules specify time or production standards.
 - Expert option: people who are experienced with the process or similar processes, often, they can provide optimistic, pessimistic and most-likely times, and they may know the variability as well.
 - Physical or conventional limitations: physical limits on performance, limits or bounds that narrow the range of the input process.
 - The nature of the process.
- The uniform, triangular, and beta distributions are often used as input models.
- **Example:** Production planning simulation.

Covariance and Correlation III

- The closer ρ is to -1 or 1, the stronger the linear relationship is between X₁ and X₂.
- A time series is a sequence of random variables
 X₁, X₂, X₃,..., are identically distributed (same mean and variance) but dependent.
 - cov(Xt, Xt + h) is the lag-*h* autocovariance
 - ► corr(Xt, Xt + h) is the lag-h autocorrelation
 - If the autocovariance value depends only on h and not on t, the time series is covariance stationary

Multivariate Input Models

- If X₁ and X₂ are normally distributed, dependence between them can be modeled by the bivariate normal distribution with parameters μ₁, μ₂, σ₁², σ₂² and correlation ρ
- To estimate μ₁, μ₂, σ²₁, σ²₂, see "Parameter Estimation" (slides 14-17)
- To estimate ρ, suppose we have n independent and identically distributed pairs (X₁₁, X₂₁), (X₁₂, X₂₂), ..., (X_{1n}, X_{2n}), then:

$$\widehat{cov}(X_1, X_2) = \frac{1}{n-1} \sum_{j=1}^n (X_{1j} - \overline{X}_1) (X_{2j} - \overline{X}_2)$$
$$= \frac{1}{n-1} \left(\sum_{j=1}^n X_{1j} X_{2j} - n \overline{X}_1 \overline{X}_2 \right)$$
$$\rho(X_1, X_2) = \frac{\widehat{cov}(X_1, X_2)}{\widehat{\sigma}_1^2 \widehat{\sigma}_2^2}$$

Time-Series Input Models

Time-Series Input Models

- If X₁, X₂, X₃,... is a sequence of identically distributed, but dependent and covariance-stationary random variables, then we can represent the process as follows:
 - Autoregressive order-1 model, AR(1)
 - Exponential autoregressive order-1 model, EAR(1)
- Both have the characteristics that: Lag-h autocorrelation decreases geometrically as the lag increases, hence, observations far apart in time are nearly independent

AR(1) Time-Series Input Models

Consider the time-series model:

$$X_t = \mu + \phi (X_{t-1} - \mu) + \varepsilon_t, \qquad t = 2, 3, \dots$$

where $\varepsilon_1, \varepsilon_2, \ldots$ are i.i.d. normally distributed with $\mu_{\varepsilon} = 0$ and variance σ_{ε}^2

▶ If X₁ is chosen appropriately, then

- X₁, X₂, ... are normally distributed with mean = μ, and variance = σ²/(1 − φ²)
- Autocorrelation $\rho_h = \phi^h$
- To estimate ϕ , μ , σ_{ε}^2 :

$$\widehat{\mu} = \overline{X}, \quad \widehat{\sigma}_{\varepsilon}^2 = \widehat{\sigma}^2 (1 - \widehat{\phi}^2), \quad \widehat{\phi} = \frac{cov(X_t, X_{t+1})}{\widehat{\sigma}^2}$$

where $cov(X_t, X_{t+1})$ is the lag-1 autocovariance

EAR(1) Time-Series Input Models

Consider the time-series model:

 $X_t = \begin{cases} \phi X_{t-1}, & \text{with probability } \phi \\ \phi X_{t-1} + \varepsilon_t, & \text{with probability } 1 - \phi \end{cases}$

where $\varepsilon_2,\,\varepsilon_3,\,\ldots\,$ are i.i.d. exponentially distributed with $\mu_\varepsilon=1/\lambda,$ and $0\leq\phi<1$

▶ If X₁ is chosen appropriately, then

- X_1, X_2, \ldots are exponentially distributed with mean $\mu = 1/\lambda$
- Autocorrelation $\rho^h = \phi^h$, and only positive correlation is allowed.

• To estimate ϕ , λ

$$\lambda = \frac{1}{\overline{X}}, \qquad \widehat{\phi} = \widehat{\rho} = \frac{\operatorname{cov}(X_t, X_{t+1})}{\widehat{\sigma}^2}$$

where $cov(X_t, X_{t+1})$ is the lag-1 autocovariance
